ABSTRACT

The primary aim of this study was to investigate the most important variables affecting the consumption of poultry white meat (PWM), as well as assessing the current situation of the production capacity of PWM in Egypt. In addition, descriptive statistics was performed for the most important variables affecting the consumption of PWM in Egypt. Besides, the most important variables influencing the consumption of PWM were determined using factor analysis model in the form of Double logarithmic regression during the period of 2000-2020. To achieve the objectives of the study, descriptive and quantitative analysis methods were used, represented by using some of multiple statistical methods and models to estimate the linear regression in double logarithmic form and the factor analysis of the most important variables influencing the consumption of PWM in Egypt. According to the results, the value of white meat amounted about 22.47 billion LE (LE = Egyptian pound) annually, representing 8.86% of the value of agricultural production during 2000-2020. Also, the results showed a significant relationship between exchange rate, per capita PWM, population, time, consumer price of municipal poultry meat and consumption of PWM in Egypt, where a change by 1% in the exchange rate and per capita PWM, population, time and consumer price of municipal poultry meat leads to an increase in the consumption of PWM by about 0.056 thousand tons, which is an inverse relationship consistent with the economic logic in association with the exchange rate variable, as well as an elevated consumption of PWM with about 0.817, 2.396 and 0.045 thousand tons, which is a direct relationship consistent with the economic logic with respect to the per capita variables of PWM, population and time, respectively, as well as the decrease in consumption of PWM by about 0.205 thousand tons, which is an inverse relationship consistent with the economic logic in relation to the consumer price variable for municipal poultry meat (according to the consumer's taste as well).

Keywords: Poultry white meat, Price, Consumption, Factor analysis, Stepwise wise regression.

Article type: Research Article.

INTRODUCTION

The poultry industry in Egypt represents an important pillar and a basic and important supporter of food security to provide protein at suitable prices to consumers. Poultry farming is an industry for large and small breeders and investors (Hussein Hnoosh 2021; Murtadha & Hammoud 2022). Moreover, self-sufficiency was achieved by more than 97% as a result of the increased local production, as well as the expansion of new poultry investment projects, manufacturing and storage areas, either by refrigeration or freezing. The value of white meat was amounted to about 22.47 billion LE annually, and about 8.86% of the value of agricultural production during the period 2000-2020. It is also an indicator of economic and social development. In addition, the per capita share of white meat was estimated about 21.5 kg annually. It must be referred to this industry absorbs over 2.5 million workers, which led to an interest in studying what are the factors affecting the consumption of white meat in Egypt. The research problem is that although there is stability in the self-sufficiency of PWM, which is about 97%, there are significant

losses for poultry breeders due to the high cost of feed, medicines, and labor, which led to a rise in poultry prices, which threatens stability in self-sufficiency and forces many small poultry farmers to leave this industry. As a result of losses and their inability to start a new cycle, especially since most of them work on the loan system, it requires attention to study the most important variables affecting the consumption of PWM in Egypt. The main objective of the study is to assess and measure the most important variables affecting the consumption of PWM in Egypt. To achieve this, the following sub-objectives were studied:

1. Identifying the current situation of PMP (PMP) in Egypt during the period of 2000-2020.
2. Identifying descriptive statistics for the most important variables used in the factor analysis model for PWM in Egypt during the period of 2000-2020.
3. Using factor analysis model of PWM in Egypt.
4. Measuring the most important variables influencing the consumption of PWM in Egypt.

MATERIALS AND METHODS

To achieve the objectives of the study, the descriptive and quantitative analysis methods were used, represented by using some multiple statistical methods and models to estimate the linear regression in double logarithmic form and the factor analysis model of the most important variables affecting consumption of PWM in Egypt during the period of 2000-2020. Factor analysis is a statistical method which aimed to interpret the coefficients of positive correlations, where statistical significance is established between various variables. In other words, factor analysis is a mathematical process that aims to simplify the correlations between the various variables included in the analysis, leading to the common factors that describe the relationship between these variables. Thus, factor analysis is a statistical method for analyzing multiple data that are linked to each other with different degrees of summary correlation in the form of independent classifications based on qualitative bases for classification, and these classification bases are examined according to both of the economic theory and the scientific logic. Where Solomon Diamond defines the objectives of factor analysis as forming and testing hypotheses, and determining the smallest number of specific factors that can explain the relationships between a large number of real phenomena and to what extent each of these factors affects each variable? He also explained that the function of factor analysis is to reduce the components of correlation tables to the lowest number possible to facilitate their interpretation. Eyzanck (1953) also showed that factor analysis has three basic objectives that must be achieved, which are describing variables, proving hypotheses, and proposing hypotheses from the initial data. Three points of view are linked to these goals, which are the nature of factors, the identification of those factors and the rotation, which are the same goals for any branch of statistics. Factor analysis tools include the following: methods of factor analysis, the problem of determining the number of factors, rotation of the axes, the definition of factors, factors rank, reproducibility of factors, and methods of analysis. In addition, the correlation matrix was analyzed by Principles' of Hotelling Method (1929) Component. Moreover, Kaiser's Orthogonal Rotation was also conducted, and the researchers chose the following conditions for accepting the factor as following: the latent root be equal to one because this degree is the most common, and at a statistical probability level of 0.05. The model depends on building structural equations that solve simultaneously using time series and ordinary least squares OLS with one, two or three stages.

Thus The multiple model depends on the following structural equation:

$$Y_t = \beta_0 + B_1X_{1t} + B_2X_{2t} + B_3X_{3t} + B_4X_{4t} + B_5X_{5t} + B_6X_{6t} + B_7X_{7t} + B_8X_{8t} + B_9X_{9t} + B_{10}X_{10t} + B_{11}X_{11t}$$

where β_0 = constant term, t = time (trend factor), the dependent variable (Y_t) was represented in consumption of PWM, while the independent variables were represented in (X_1) consumer price of PWM, (X_2) per capita PWM, (X_3) consumer price of municipal poultry meat, (X_4) consumer price of red meat, (X_5) Consumer price of fish, (X_6) exchange rate, (X_7) population, (X_8) national income, (X_9) import price of frozen white meat, (X_{10}) import price of frozen red meat, and (X_{11}) time. In addition, The research used many published and unpublished data issued by the Economic Affairs Sector, the Ministry of Agriculture and Land Reclamation through the use of various preparations for the Bulletin of Agricultural Statistics for Poultry wealth and the publication of the food balance, as well as the publication of prices of materials, food products and services for the Central Agency for Public Mobilization and Statistics, in addition to the assistance of some research, published in scientific journals and academic letters related to the topic of the study.

RESULTS AND DISCUSSION

This section of study includes results and discussion according to research objectives as follows:

Results regarding the First objective, which provides for identifying the current situation of poultry meat production (PMP) in Egypt during the period of 2000-2020.

Tables 1 and 2 which display summary statistics for poultry meat, are considered as one of the most important food commodities, since the average production value for poultry meat amounted to about 22.47 billion LE or about 8.86% of the value of agricultural production during 2000-2020, and it is also an indicator of economic and social developments. The animal production sector in general and the production of poultry meat in Egypt in particular have an important place. Thus this part of the research aimed to identify the current situation of PMP in Egypt during 2000-2020 by studying several points represented in evolution of the value of each Agriculture production, poultry meat and chicken meat production, and finally evolution of production and consumption of chicken meat in Egypt.

Development of the value of national agricultural production

Table 1 indicates that the average value of agricultural production during 2000-2020 was estimated at 253 billion L.E., and by studying the evolution of the value of national agricultural production. It was found that this average reached its maximum value in 2020 (about 596 billion L.E.), while the lowest value at the beginning of the study period was about 71.7 billion L.E.

Development of the value of PMP

Table1 shows that the average value of poultry meat amounted to 22.5 billion LE during 2000-2020, and it was found that this average lies between the lowest and highest value, which amounted to 3.5 billion LE in 2000 and 67 billion LE in 2020.

Table 1. Relative importance of total value of poultry meat production (PMP) in Egypt during 2000-2020.

| years | Agri. Pro | Total poultry meat | % | Total chicken | Rate (%) | Rabbits | Ducks | Geese | Pigeons (pair) | Turkey |

Development of the value of chicken meat production

In addition, the data in the same table also indicate that the average value of chicken meat amounted to about 14.6 billion LE during 2000-2020, and this average lies between the lowest and highest limits, which amounted to about 2.4 billion LE in 2000 reached 60.4 billion LE in 2020. Furthermore, the value of chicken meat represents about 64.86% of the value of PMP.

The development of production and consumption of chicken meat in Egypt

Table 2 shows that the average production of chicken meat in Egypt during 2000-2020 was estimated by 954 thousand tons. The amount of meat produced in Egypt apparently has been steadily increasing from about 548 thousand tons in 2000 to about 2033 in 2020. It appears that the average domestic consumption is estimated by 974.95 thousand tons during 2000-2020. The lowest value of consumption in 2000 was about 548 thousand tons, while it reached its maximum in 2020 by about 1951 thousand tons. As a result of fluctuation in both production and consumption of chicken meat, the self-sufficiency ratio reached the lowest in 2014 by about 91%, while reached its highest in 2002 by about 104%. Moreover, it appears that the average population is estimated by 80 million people during 2000-2020. It was minimum in 2000 with about 63 million people, while reached its maximum in 2020 with about 102 million people. As for the average per capita of chicken meat, it varied between 7.36 kg in 2000 as a minimum and about 13.12 kg in 2020 as a maximum, with average estimated about 8.85 kg during 2000-2020.

Results regarding the second objective, which provides for identifying the descriptive statistics for the most important variables used in the factor analysis model for PWM in Egypt during the period of 2000-2020

Table 3 shows the descriptive statistics of the variables that used in the factor analysis model for PWM in Egypt during the period of 2000-2020, which the dependent variable was represented in consumption of PWM and the independent variables were represented in consumer price of PWM, PWM consuming per capita, the consumer prices of municipal poultry meat, red meat and tilapia, exchange rate, population, national income, import price of frozen white meat and frozen red meat, and time. Once the average consumption of chicken was about 974.95, and its maximum value was 1951 thousand tons, its minimum value was 548 thousand tons (\pm SD = standard deviation = 367.86). In addition, the average price of chicken was 16.98 LE kg⁻¹, with a maximum of about 32.92 LE kg⁻¹ and a minimum of 5.12 LE kg⁻¹, with a standard deviation 9.64. Furthermore, the average per capita share of poultry meat was 8.7 kg year⁻¹ and its maximum value was 13.3 kg year⁻¹, while its minimum value was 5.5 kg year⁻¹, (\pm SD = 2.21). Moreover, the average price of municipal chicken was 19.87 LE kg⁻¹, with a maximum of about 40.8 LE kg⁻¹ and its minimum was 6.84 LE kg⁻¹ (\pm SD = 11.81).

Besides the average price of red meat was about 62.43 pounds kg⁻¹, with a maximum of 146.76 LE kg⁻¹ and a minimum of 16.37 LE kg⁻¹ (\pm SD = 46.44). The average price of tilapia was estimated at 16.35 LE kg⁻¹, while its maximum was 32.95 LE kg⁻¹ and a minimum at 6.98 LE kg⁻¹, (\pm SD = 9.34) and a minimum of 3.48 LE kg⁻¹ (\pm SD = 4.68). Equally important, the average population was 80.38 million people, its maximum was 102 and a minimum of 63.98 (\pm SD = 11.58). Also, the average national income amounted to 2.21 billion LE, with a maximum of 8.14 billion LE, and a minimum of 0.32 billion LE (\pm SD = 2.4). Moreover, the average import price of frozen chicken was 24 LE kg⁻¹, with a maximum of 78.27 LE kg⁻¹ and a minimum of 7.24 LE kg⁻¹ (\pm SD = 20). In addition, the average of import price of frozen red meat was estimated at 31.76 LE kg⁻¹, while its maximum was 79.28 LE kg⁻¹ and its minimum 5.56 LE kg⁻¹ (\pm SD 25.82). It becomes clear that from Jargue-Bera value, that both of the available consumption of chicken meat, the exchange rate, and the import price of frozen chicken were follow a normal distribution. Furthermore, the value of the standard deviation indicates that the available consumption of chicken meat is the most volatile, while the per capita consumption of chicken meat is the least volatile (Table 3).

Results regarding the third objective, which provides for using factor analysis model of PWM in Egypt

Correlation Matrix

Table 4 shows the coefficients of correlation matrix between the variables, which is the first step to examine the relationships between them in the factor analysis, where the relationship between the variables is more than 0.30, which indicates the possibility of using the main components method in the analysis. We also found that the majority of the values are significant at 0.05.

Table 2. Some productive and economic variables for chicken meat in Egypt during 2000-2020.

| Year | Production | Consumption | Gap | Self- sufficiency % | Pure food | Population | Per capita |
|---------|--------------|-------------|------|---------------------|-----------|------------|------------|
| | Thousand ton | | | | | million | Kg |

Bartlett's Test

Bartlett's test is used to test whether the original correlation matrix is a unit matrix or not. If this matrix is not a unit matrix, this indicates that there are relationships between the variables, and this is what is required when using the main components method. Table 5 indicates that the value of Bartlett's test equals 552.079, which indicates that the test is statistically significant at 0.01. Therefore, we conclude that the original correlation matrix is of the unit matrix type. We also noticed from the table that the value of Kaiser-Meyer-Olkin (KMO 1974) is equal to 0.875, as its statistical significance. Therefore, it is acceptable, since the minimum value for KMO is 0.60 and this means that the measurement is good, and that the factor analysis has reduced the factors with high quality.

Table 5. KMO and Bartlett's Tests.

| Kaiser-Meyer-Olkin Measure of Sampling Adequacy | | 0.875 |
|---|--------------------|---------|
| | Approx. Chi-Square | 552.079 |
| Bartlett's Test | df | 55 |
| | Sig. | 0.000 |

Communalities

Table 6 shows the amount of communalities for the variables that represent the percentage of variance that is explained by the extracted factors for these variables. If the amount of communalities is high, this indicates that the extracted factors explain a high percentage of the variance of the variables (Table 6). Thus, the extracted factors explain a high percentage of the variance of the variables.

Determining the main components of the model using Kaiser and Cattell test

Kaiser test was used to determine the factors whose distinct roots exceed than correct one. Table 7 depicts the total variance explained, which the first factor has distinct roots more than the correct one, and it explains about 86.507% of the total variance, as well as the use of Cattell's test for the selection of factors using the Scree Plot. Fig. 1 showed that the diffusion pattern is clearly refracted after the first factor, that is, between the first and second factors, changing its direction to the horizontal, and from this it becomes clear that the first factor explains most of the variance in comparison with the rest of the factors and this factor can be adopted according to Cattell's view, who agreed with Kaiser view.

Table 6. Distinctive roots of principal components and additive variance after rotation Communalities.

The degree of saturation of the factors

Table 8 depicts the degree of saturation belonging to the first factor. Thus it has strong relationships with ten out of eleven variables, which can be called the basic and alternative factors that affect the consumption of white

poultry meat. It becomes clear that population variable has the highest saturation by 0.997, then consumer price of red meat, consumer price of municipal chicken meat, consumer price of fish, national income, import price for frozen red meat, import price for frozen white chicken meat, consumer price of PWM, exchange rate, time, with a degree of saturation amounted to 0.996, 0.991, 0.990, 0.988, 0.987, 0.979, 0.974, 0.910, 0.905, respectively. This is logical with the current situation. In addition, Table 8 illustrates that the second factor has strong relationships with only one variable, which is the per capita share of white chicken meat with a saturation by about 0.959.

Table 8. Rotated Component Matrix.

| Variables | Component | |
|-----------------|-----------|-------|
| | 1 | 2 |
| X ₇ | 0.997 | |
| X ₄ | 0.996 | |
| X ₃ | 0.991 | |
| X ₈ | 0.990 | |
| X ₅ | 0.988 | |
| X ₁₀ | 0.987 | |
| X ₉ | 0.979 | |
| X ₁ | 0.974 | |
| X ₆ | 0.910 | |
| X ₁₁ | 0.905 | |
| X ₂ | | 0.959 |

Consumer price of municipal poultry meat X₃, exchange rate X₆, population X₇, time X₁₁ and the method of exclusion is done by excluding the variables that are larger than 0.100. In addition, variables with a probability value of F test is less than 0.05. Table 10, estimates the consumption function of PWM in the double logarithmic form, and the model was formulated in the following mathematical form:

$$\log Y = \log a + B_2 \log X_2 + B_3 \log X_3 + B_6 \log X_6 + B_7 \log X_7 + B_{11} \log X_{11}$$

where:

Y= consumption for PWM (thousand ton⁻¹)

X₂ = per capita share of PWM (kg year⁻¹).

X₃ = consumer price of municipal poultry meat (LE kg⁻¹).

X₆ = exchange rate (LE/\$), X₇ = population (thousand people), X₁₁ = time.

Table 10. Values of the double logarithmic regression coefficients for the most important variables affecting consumption of PWM in Egypt.

Source: Results of the statistical analysis of SPSS program.

By estimating the model using the Step-Wise Regression analysis method in the double logarithmic form during the period of 2000-2020, equation 1 appears the significant effect of the exchange rate on the consumption of PWM in Egypt, where the results showed that a change of 1% in the price of the exchange leads to an increase in the consumption of PWM by about 0.585 thousand tons, which is inconsistent with the economic logic. In addition, F value indicates the statistical significance at 1%. Moreover, By studying equation 2, we can find the significant effect of the exchange rate and the per capita share of PWM on the consumption of PWM in Egypt, where the results showed that a change of 1% in the exchange rate and per capita share of PWM lead to an increase in the consumption of PWM by 0.445 and 0.660 thousand tons, respectively. In addition, the value of the coefficient of determination (R²) indicates that about 91.3% of the changes that occur in the availability of consumption PWM are due to factors which reflect in the exchange rate and the per capita share of PWM. F value indicates the statistical significance of the model.

Equation 3 exhibits the significant relationship of exchange rate, per capita share of PWM, and the population on the consumption of PWM in Egypt. The results showed that a change of 1% in the exchange rate leads to an increase in the consumption of PWM by about 0.029 thousand tons, which exhibits an inverse relationship and is consistent with the economic logic, as well as an increase in the consumption of PWM by about 0.817 and 1.653 thousand tons per capita of PWM and the number of the population, respectively. R² value refers 99.4% of the changes that occur in the availability for consumption of PWM, are due to exchange rate factor, the per capita share of PWM and the population.

In addition, F value indicates the statistical significance of the model. Moreover, equation 4 shows the significant effect of the per capita share of PWM, population on the consumption of PWM in Egypt by about 0.805 and 1.569 thousand tons, respectively. The direct relationship is consistent with the economic logic. R₂ indicates that

about 99.4% of the changes that occur in the availability for consumption of PWM are reflects by the per capita factor of meat white poultry and population. F value indicates the statistical significance of the model. Equation 5 illustrates that there is a significant effect of per capita share of PWM, population, and time on the consumption of PWM in Egypt at level of 5%.

Alteration of 1% in the per capita share of PWM, population, and time leads to increasing in the consumption of PWM by about 0.844, 1.263 and 0.056 thousand tons, respectively which is consistent with the economic logic. Determination factor (R^2) indicates that about 99.6% of the changes that occur in the availability for consumption of PWM are due to per capita poultry white meat, the number of population and time. F value indicates the significance of the model at level of 5%. Equation 6 shows the significant effect of per capita share of PWM, population, time, consumer price of municipal poultry meat on the consumption of PWM in Egypt, where the results showed that a change of 1% in the per capita share of PWM and the population and time leads to an increase in the consumption of PWM by about 0.808, 1.966 and 0.049 thousand tons, respectively and consistent with the economic logic.

In addition, a change by 1% in consumer price of municipal poultry meat leads to decrease in the consumption of PWM by about 0.150 thousand tons, which is an inverse relationship consistent with the economic logic. Determination factor (R^2) indicates that about 99.7% of the changes that occur in the available consumption of PWM are due to selected factors. F value indicates significance of the model. Equation 7 exhibited the significant relationship of coefficients. It is considered as the best equation, since it includes a large number of the most important variables affecting consumption of PWM. Furthermore, it is consistent with the economic logic.

The results showed that a change of 1% in exchange rate and consumer price of municipal poultry meat, lead to decrease in consumption of PWM by about 0.056 and 0.205 thousand tons, respectively, with an inverse relationship. It is consistent with economic logic, as well as a change of 1% in a per capita share of PWM, population, time lead to increase in consumption of PWM by about 0.817, 2.396 and 0.045 thousand tons, respectively. Thus there is a direct relationship between them and is consistent with economic logic. In addition, determination factor (R^2) indicates that about 99.8% of the changes that occur in the available consumption of PWM are due to the previous factors. F value indicates the statistical significance of the model at 1% level.

CONCLUSION

Depending on the results, there are some recommendations for decision-makers illustrated in providing production requirements for the local poultry industry, especially corn, as it is an essential component of poultry nutrition, through horizontal agricultural expansion for feed production and establishing farms for poultry production. Beside, giving farmers appropriate price to encourage them to cultivate important feed crops. In addition, providing accurate data of poultry industry for researchers to put suitable alternatives to make PWM available to consumers at an appropriate price.
